Interpreting the genomic landscape of speciation: insights from a radiation of monkeyflowers

Sean Stankowski

University of Sheffield

Host: Nick Barton

A major goal of speciation genomic studies is to infer the basis of reproductive isolation from patterns of genome-wide variation. However, Interpreting the genomic landscape of speciation is difficult because patterns of variation can be shaped by many factors, some of which have nothing to do with speciation, per se. Recent work has suggested that background selection (BGS) is an important confounding factor that may lead to erroneous conclusions about the genomic location of barrier loci. In response, several authors have proposed methods for controlling for its effect. One such method involves using the correlation in differentiation across multiple closely related taxa as a baseline in outlier detection the assumption that correlated genomic landscapes arise primarily due to BGS. Using empirical and simulated data from a radiation of monkeyflowers, I will argue that (i) BGS is unlikely to be major factor confounding speciation genomic studies and (ii) in attempting to control for it, we may actually be discarding the polygenic signature of adaptation and speciation.

Wednesday, February 19, 2020 12:30pm - 01:30pm

I22 Lakeside View (I22.01)

This invitation is valid as a ticket for the ISTA Shuttle from and to Heiligenstadt Station.

Please find a schedule of the ISTA Shuttle on our webpage:

<https://ista.ac.at/en/campus/how-to-get-here/> The ISTA Shuttle bus is marked ISTA Shuttle (#142) and has the Institute Logo printed on the side.
